

## REGIONAL MATH'S OLYMPIAD (FIRST ROUND) 2011

### SOLUTIONS

1. Let ABCD be a square of side 1 and P, Q, R, S be points inside the square such that APB, BQC, DSA, CRD are equilateral triangles. Compute the area of PQRS [12]

**Sol:**

Dropping  $PE \perp AB$ ,  $QF \perp BC$ ,  $RG \perp DC$ ,  $SH \perp AD$ .

Let the point of their intersection be 'O'.

$$PE^2 + AE^2 = AP^2$$

$$PE^2 = 1^2 - (0.5)^2 \quad [\perp \text{ of an eq. } \Delta \text{ bisects the opp. side}]$$

$$PE = \sqrt{0.75} = 0.5\sqrt{3}$$

$$\text{Similarly } RG = 0.5\sqrt{3}$$

Since G and E are mid-points of AB and CD,

$$GE \parallel AD \parallel BC.$$

$$PG + PE = AD$$

$$PG + 0.5\sqrt{3} = 1$$

$$PG = 1 - 0.5\sqrt{3}$$

$$\text{Similarly } RE = 1 - 0.5\sqrt{3}$$

$$\therefore PG = RE$$

$$PR + PG + RE = BC$$

$$PR + 2 - \sqrt{3} = 1$$

$$PR = \sqrt{3} - 1$$

$$QF^2 + FC^2 = QC^2$$

$$QF^2 + (0.5)^2 = 1^2 \quad [\perp \text{ bisects the opp. sides}]$$

$$QF^2 = 0.75$$

$$QF = 0.5\sqrt{3}$$

$$\text{Similarly, } SH = 0.5\sqrt{3}$$

$$QH + QF = DC$$

$$QH + 0.5\sqrt{3} = 1$$

$$QH = 1 - 0.5\sqrt{3}$$

$$\text{Similarly } SF = 1 - 0.5\sqrt{3}$$

$$SF + QH + QS = 1$$

$$2 - \sqrt{3} + QS = 1$$

$$QS = \sqrt{3} - 1$$

Since  $FH \parallel DC$ ,

$$GO = 0.5 = OE = OH = OF$$

$$PO + GP = GO$$

$$PO + 1 - 0.5\sqrt{3} = 0.5$$

$$PO = 0.5\sqrt{3} - 0.5$$

$$\text{Similarly } PO = OQ = 0.5(\sqrt{3} - 1)$$

$$OP^2 + OQ^2 = PQ^2$$

$$0.5^2(\sqrt{3} - 1)^2 + 0.5^2(\sqrt{3} - 1)^2 = PQ^2$$

$$2 \left[ \frac{0.25}{100} (4 - 2\sqrt{3}) \right]$$

$$2 - \sqrt{3} = PQ^2$$

$$PQ = \sqrt{2 - \sqrt{3}}$$

Similarly,

$$SR^2 = 2 - \sqrt{3}$$

$$SR = \sqrt{2 - \sqrt{3}}$$

Area of square (Since opp. sides are equal, diagonals bisect at  $90^\circ$  and are equal)

$$= \left[ \sqrt{2 - \sqrt{3}} \right]^2$$

$$= 2 - \sqrt{3}$$

2. Let ABC be an acute angled triangle and D be the foot of perpendicular from A on BC. Let AD meet the ortho-circle of the triangle ABC in K and let H be the orthocenter of the triangle ABC. Prove that HD = DK. [10]

**Sol:**

In  $\Delta HND$  and  $\Delta HMD$

$HN = HM$  (Radius)

$HD = HD$  (Common)

$\angle HDN = \angle HDM = 90^\circ$  (each)

$\Delta HND \cong \Delta HMD$  [By R.H.S congruency]

$$\Rightarrow \angle 3 = \angle 4 \quad [\text{By C.P.C.T.}] \quad \dots(1)$$

$$ND = DM \quad [\text{By C.P.C.T.}]$$

Now, In  $\Delta NDK$  and  $\Delta MDK$

$$ND = MD \quad [\text{from above C.P.C.T}]$$

$$\angle NDK = \angle MDK = 90^\circ \text{ each}$$

$$DK = DK \quad (\text{common})$$

$$\Delta NDK \cong \Delta MDK \quad [\text{By S.A.S. congruency}]$$

$$\angle 9 = \angle 10 \quad [\text{By C.P.C.T.}] \quad \dots (2)$$

$$NK = MK \quad [\text{By C.P.C.T.}]$$

In  $\Delta NHM$  and  $\Delta NKM$

$$NH = HM \quad [\text{Radius}]$$

$$NK = MK \quad [\text{From C.P.C.T. (2)}]$$

$$HK = HK \quad [\text{Common}]$$

$$\Delta NHM \cong \Delta NKM \quad [\text{By S.S.S. congruency}]$$

$$\therefore \angle 3 + \angle 4 = \angle 9 + \angle 10 \quad (\text{By C.P.C.T.}) \quad \dots(3)$$

Now

from (1) and (2) C.P.C.T.

$$\angle 3 = \angle 4$$

$$\angle 9 = \angle 10$$

$\therefore$  Equation (3) becomes

$$\angle 3 + \angle 3 = \angle 9 + \angle 9$$

$$2 \angle 3 = 2 \angle 9$$

$$\Rightarrow \angle 3 = \angle 9 \quad \dots (4)$$

In  $\Delta NHD$  and  $\Delta NKD$

$$\angle 3 = \angle 9 \quad [\text{From 4}]$$

$$\angle NDH = \angle NDK = 90^\circ \text{ each}$$

$$ND = ND \quad [\text{common}]$$

$$\Delta NHD \cong \Delta NKD$$

$$\therefore HD = DK$$

Hence the result.

3. If  $a, b, x, y$  are four distinct real numbers such that  $a^2 - b = b^2 - c = c^2 - d = d^2 - a$ , prove that  $(a + b)(b + c)(c + d)(d + a) = 1$  [10]

**Sol:**

$$a^2 - b = b^2 - c \quad [\text{Given}]$$

$$a^2 - b^2 = b - c.$$

$$(a - b)(a + b) = b - c$$

$$(a + b) = \left[ \frac{b - c}{a - b} \right] \quad \dots(1)$$

$$b^2 - c = c^2 - d \quad [\text{Given}]$$

$$b^2 - c^2 = c - d$$

$$(b - c)(b + c) = c - d$$

$$b + c = \frac{c - d}{b - c} \quad \dots(2)$$

$$c^2 - d = d^2 - a \quad (\text{Given})$$

$$c^2 - d^2 = d - a$$

$$(c - d)(c + d) = (d - a)$$

$$(c + d) = \left[ \frac{d - a}{c - d} \right] \quad \dots(3)$$

$$d^2 - a = a^2 - b \quad (\text{Given})$$

$$d^2 - a^2 = a - b$$

$$(d - a)(d + a) = a - b.$$

$$d + a = \frac{a - b}{d - a} \quad \dots(4)$$

On multiplying (1), (2), (3), (4)

$$(a + b) (b + c) (c + d) (d + a) = \left( \frac{\cancel{b-c}}{\cancel{a-b}} \right) \left( \frac{\cancel{c-d}}{\cancel{b-c}} \right) \left( \frac{\cancel{d-a}}{\cancel{c-d}} \right) \left( \frac{\cancel{a-b}}{\cancel{d-a}} \right)$$

$$\therefore (a + b) (b + c) (c + d) (d + a) = 1.$$

Hence proved.

4. Find all pairs of integers (x, y) which satisfy the equation

$$y^2(x^2 + 1) + x^2(y^2 + 16) = 448. \quad [15]$$

**Sol:**

$$y^2 x^2 + y^2 + x^2 y^2 + 16x^2 = 448$$

$$2x^2 y^2 + y^2 + 16x^2 = 448$$

$$2x^2 y^2 + y^2 = 448 - 16x^2$$

$$y^2 (2x^2 + 1) = 16(28 - x^2)$$

If  $y^2 = 16$  then  $2x^2 + 1 = 28 - x^2$

$$y^2 = 4 \times 4 \quad \text{then} \quad 2x^2 + x^2 = 28 - 1$$

$$y^2 = \sqrt{4^2} \quad \text{then} \quad 3x^2 = 27$$

$$y = \sqrt{4^2} \quad \text{then} \quad x^2 = 9$$

$$y = \pm 4 \quad \text{then} \quad x = \pm 3$$

If  $y^2 = 28 - x^2$  then  $2x^2 + 1 = 16$

$$y^2 + x^2 = 28 \quad \text{then} \quad 2x^2 = 16 - 1$$

$$y^2 + x^2 = 28 \quad \text{then} \quad 2x^2 = 15$$

$$x^2 + y^2 = 28 \quad \text{then} \quad x^2 = 15/2$$

$$x^2 + y^2 = 28 \quad \text{then} \quad x = \pm \sqrt{15/2}$$

Since in this case, values of x are not integers, this, it is rejected

$$\therefore x = \pm 3 \quad y = \pm 4$$

$$\therefore \text{possible pair} = (3, 4); (3, -4); (-3, 4); (-3, -4).$$

5. Prove that for each positive integer  $m$ , the number  $9 \cdot 2^m$  can be written as a sum of three squares of positive integers. [12]

**Sol:**

$$9 \cdot 2^m$$

For  $m = 1$

$$9 \cdot 2 = 18 \quad \rightarrow \quad 4^2 + 1^2 + 1^2.$$

By induction, we can assume for  $m = k$

$$9 \cdot 2^k = x^2 + y^2 + z^2.$$

Now, we have to prove for

$$m = k + 1$$

$$2 \cdot 9 \cdot 2^k = x^2 + y^2 + z^2$$

For  $m = 2$

$$9 \cdot 2^2 = 36 \quad \rightarrow \quad 4^2 + 4^2 + 2^2$$

By induction we can assume for  $m = k + 1$

$$9 \cdot 2^{k+1} = x^2 + y^2 + z^2$$

$$2 \cdot 9 \cdot 2^k = x^2 + y^2 + z^2$$

Hence Proved.

6. Determine how many distinct integers are there in the set

$$\left\{ \left[ \frac{1^2}{1998} \right], \left[ \frac{2^2}{1998} \right], \left[ \frac{3^2}{1998} \right], \dots, \left[ \frac{1998^2}{1998} \right] \right\}$$

Here  $[x]$  denotes the greatest integer less than or equal to  $x$ . [17]

**Sol:**

$$\left\{ \left[ \frac{1^2}{1998} \right], \left[ \frac{2^2}{1998} \right], \left[ \frac{3^2}{1998} \right], \dots, \left[ \frac{1997^2}{1998} \right], \left[ \frac{1998^2}{1998} \right] \right\}$$

$$\text{Upto } \left[ \frac{1^2}{1998} \right] = \left[ \frac{2^2}{1998} \right] = \dots = \left[ \frac{44^2}{1998} \right] = 0$$

$$\text{Upto } \left[ \frac{45^2}{1998} \right] = \left[ \frac{46^2}{1998} \right] = \dots = \left[ \frac{63^2}{1998} \right] = 1$$

$$\therefore \left[ \frac{64^2}{1998} \right] = 2 \text{ and so on upto } \left[ \frac{x^2}{1998} \right] \text{ where } x = 999 \text{ and distinct integers are } \{0, 1, 2, 3,$$

..... 499, \} which are 500 in numbers

$$\text{Now } \frac{(1000)^2}{1998} = \frac{1000000}{1998}$$

$$\frac{999^2}{1998} = \frac{998001}{1998} \text{ and}$$

There difference is  $(1000)^2 - (999)^2 > 1998$

$$\text{so } \frac{(1000)^2 - (999)^2}{1998} > 1$$

and onwards.

$\therefore x = 1000$  and onwards every term will have a unique GINT, which can be  $1998 - 999 = 999$

numbers of unique integers. And the previous integers are 500 in number

$\therefore$  The total integers are  $999 + 500 = 1499$ .

7. How many 6 digit numbers abcdef are there consisting of the digits 0, 1, 2, 3, 4, 5 each exactly once and satisfying the condition  $a + f = b + e = c + d$  [12]

**Sol:**

$$0 + 5 = 1 + 4 = 2 + 3 = 5$$

The supplement of 0 = 5 and vice versa

The supplement of 1 = 4 and vice versa

The supplement of 2 = 3 and vice versa

The lakh's place can have any digit except 0.  $\therefore$  5 possibilities.

Let's fix any one of the numbers at this place.

Thus, the one's digit can have only one digit i.e. its supplement

Now we are left with  $6 - 2 = 4$  digits.

The 10,000's place can have any of the 4 digits. Lets fix any 1 number of the remaining at this place.

Thus, the 10's digit will have only one digit i.e. its supplement.

Now we are left with only  $4 - 2 = 2$  digits

the 1000's place can have any one of these two. Lets fix one of these there. Now we are left with only one digit.

$\therefore$  By rule of multiplication, we get,

Total numbers possible =  $5 \times 4 \times 2 = 40$  numbers.

**8.** How many ordered triples (a, b, c) of integers are there such that

(i)  $1 \leq a \leq 10, 1 \leq b \leq 10, 1 \leq c \leq 10$  and

(ii)  $a \leq b \leq c$ ?

[12]

**Sol:**

$$1 \leq a, b, c \leq 10$$

$$a \leq b \leq c$$

$$\text{when } a = 1$$

$$a = 1, c = 10$$

$$1 \leq b \leq 10 \quad \boxed{10} \text{ cases}$$

$$a = 1, c = 9$$

$$1 \leq b \leq 9 \quad \boxed{9} \text{ cases}$$

$$a = 1, c = 8$$

$$1 \leq b \leq 8 \quad \boxed{8} \text{ cases}$$

$$a = 1, c = 7$$

$$1 \leq b \leq 7 \quad \boxed{7} \text{ cases}$$

$$a = 1, c = 6$$

$$1 \leq b \leq 6 \quad \boxed{6} \text{ cases}$$

$$a = 1, c = 5$$

$$1 \leq b \leq 5 \quad \boxed{5} \text{ cases}$$

$$a = 1, c = 4$$

$$1 \leq b \leq 4 \quad \boxed{4} \text{ cases}$$

$$a = 1, c = 3$$

$$1 \leq b \leq 3 \quad \boxed{3} \text{ cases}$$

$$a = 1, c = 2$$

$$1 \leq b \leq 2 \quad \boxed{2} \text{ cases}$$

$$a = 1, c = 1$$

$$1 \leq b \leq 1 \quad \boxed{1} \text{ cases}$$

$$\text{Total cases} = 10 + 9 + 8 + 7 + 6 + 5 + 4 + 3 + 2 + 1 = 55 \text{ cases.}$$

Similarly

Total cases

For  $a = 2$

45

For  $a = 3$

36

For  $a = 4$

28

For  $a = 5$

21

|            |            |
|------------|------------|
| For a = 6  | 15         |
| For a = 7  | 10         |
| For a = 8  | 06         |
| For a = 9  | 03         |
| For a = 10 | 01         |
| For a = 1  | <u>55</u>  |
|            | <u>220</u> |

∴ The total possible triplets are 220.
